

Engineering Classification of Melbriges
and Similar Block-in-Matrix Rocks —
an Initial Step toward Rockmass Characterization

Ed Medley

Friday Nov 13, 1992

Definitions:

Mélange

Block-in-Matrix rock.

- 1. Mélange (mélange) = Fr. for 'mixture'

A body of rock mappable at a scale of 1:24000 or smaller, characterized by a lack of internal continuity, of contacts, or strata, and by the inclusion of fragments and blocks of all sizes, both exotic and native, embedded in a fragmental matrix of finer grained material

(Glossary of Geology, 1987)

or, as defined by Cowen, 1985

a mélange is:

'block-in-mudstone chaos'

2. A definition of 'block-in-matrix rock'

could be constructed like:

'A mixture of relatively large fragments of material within a banded matrix of finer texture'

'Block-in-Matrix rock' is abbreviated

to: 'bimrock'

4. 2. Malangus are difficult to sample and test:

exploring

..... dreaming....
but value of data?

ON	Cost	Cost	Cost
Cost	Cost	Cost	Cost
Cost	Cost	Cost	Cost
Cost	Cost	Cost	Cost

reality: . . .

Outline of the Research Problem

- Scott Dam built on melange.
- Dam is concrete gravity, built 1920's. Stability under DSAD review 710 years.
- Dam founded on 2 'bands' of melange, each of which has a different proportion of 'stronger' blocks within 'weaker' matrix.
- F.S. ≈ 0.6 (sliding) if strength of matrix alone is used.
- Proposed approach is to assign overall rockmass strengths to melange bands on the basis of volumetric proportion of the 'stronger' blocks in the 'weaker matrix'.
- This approach is novel.

Fundamental Research Premise

There is a primary relationship between the volumetric proportion of blocks in a matrix and the overall strength of the block-in-matrix (bimrock) composite.

Approaches taken to research the basic premise :

1. Physical modelling (Eric Lindqvist)
2. Numerical modelling (Te-Chih Ke)
3. Empirical - Ed Medley.

ie :

an attempt to understand me lange behaviour by reviewing practical experience and field study of melange and similar bimrocks

Proposed Research approach :

1. Construct an engineering classification for bimrocks
2. Use the engineering classification as a means to broaden literature and case history research beyond melanges
3. Adapt an existing Rockmass Classification scheme to include consideration of block volume proportions
4. Use modified Rockmass Classification to correlate block volume proportions to rockmass C, ϕ etc. for any given bimrock type
5. Predict C, ϕ for some Franciscan Complex melanges and test predictions using case history and field data.

Some aspects of block-in-matrix materials

As defined previously, a block-in-matrix material

is:

' a mixture of relatively larger fragments within a bonded matrix of finer texture '

or:

- No genesis implied
- weaker blocks may be enclosed within a stronger matrix
- blocks of fine grained material can be included within a matrix of coarse grained material.

Examples of bim materials. :

- concrete
- glacial till (lodgement)
- colluvium
- breccias
- saprolites
- malange

Some characteristics of block-in-matrix materials:

1. Concrete

Various 'mixture models' for concrete are of the form:

$$E_{\text{conc}} = f(c_m, E_m, c_a, E_a)$$

m = matrix
 a = aggregate
 c = content
 E = modulus

also, in modelling a simple mixture, Eric Lindqvist[†] found (1972):

2. Franciscan Complex melange

Slopes in Franciscan Complex melanges appear to be more stable where there is a higher proportion of blocks in the sheared matrix

(Savina, 1982; Troutman, 1976; Peterson, 1979)

3. Debris Flow modelling

Rodine & Johnson (1976) show that a model slurry is strengthened by a higher proportion of inclusions.

ie: For 2 sizes of spheres, strength increase occur at 60% volume proportion.

But for a well graded distribution, strength increases at 95% volume proportion

Discontinuities in bimrock fabric

In addition to blocks and matrix, discontinuities influence bimrock behaviour.

Discontinuities occur in the matrix

Discontinuities occur in the blocks

Discontinuities occur in both blocks and matrix

However, the presence of discontinuities in the weaker component may be more critical.

Engineering Classification of Birrocks

- d - discontinuity spacing is a measure of spacing.

Example birrocks:

block in closely jointed matrix: melange
volcanic breccia
mylonite

Use of Blinck Classification

- The classification will allow literature and case history research to be broadened, beyond study of melange
- allows correlation of volumetric proportion of blocks to e, f within Blinck categories.
- can be enhanced by geological descriptors:
 - eg: 'graywacke blocks in closely jointed argillite matrix'

Further Research Steps

1. Adapt an existing Rockmass Classification Scheme to include volumetric proportions of blocks
2. Review case histories to generate c_p & ϕ correlations with volumes of blocks for binrock classification categories.

e.g.:

3. Study failure modes for binrocks
4. Study weak block / strong matrix implications
5. Predict c_p & ϕ for Transition mélange and test against experience / field observations.

Discrimination of bimrocks

- In geology, 'fragmentites' or 'rudrocks' are classified on the basis of lithology, particle shapes, sizes, etc. \Rightarrow complexity
- For engineering purposes, one could discriminate bimrocks on the basis of property contrasts between blocks and matrix.
 - e.g. : - Strength contrasts
 - particle size contrasts.

For strength contrasts, say :

$$K_1 > \frac{(I_u)_{\text{block}}}{(I_u)_{\text{matrix}}} > K_2$$

blocks weaker than matrix

blocks stronger than matrix

or:

$$n_1 > \frac{(\tan \phi)_{\text{block}}}{(\tan \phi)_{\text{matrix}}} > n_2$$

For example, at Scott Dam $\phi_{\text{greywacke}} \sim 55^\circ$
 $\phi_{\text{argillite}} \sim 30^\circ$

$$\therefore \frac{(\tan \phi)_b}{(\tan \phi)_m} = \frac{(\tan 55)}{(\tan 30)} \approx 2.5$$

For material size contrasts, could use a particle size distribution concept.

ie:

This distribution is 'gap-graded', (clear cut).

Not so obvious:

For a 'well graded' binrock, define a 'uniformity criterion'.

ie:
$$\frac{d_{60}}{d_{10}} > 10 \quad ??$$

For above: $\sim \frac{300\text{mm}}{20\text{mm}} \sim 15 \quad \checkmark$ etc.

RMR classes:

RMR	81-100	61-80	41-60	21-40	0-20
	v. good rock	good rock	fair rock	poor rock	v. poor rock

* bimocks? →

* Bieniawski (1970) shows 350 case histories. 10 of these is breccia and mylonite. RMR range 37 → 9.

It may be possible to modify RMR method to accommodate bimocks (as classified in presentation), with inclusion of a measure of volumetric properties.

ie:

Indicator (RMR)	Rating.	Indicator Bimock RMC.
$\sum_{i=1}^n$ Intact Rock	15	$\bar{\sum}_{i=1}^n$ blocks
drill core RQD	20	Volume of matrix
discontinuity spacing	20	block discont. spacing
discontinuity condition	30	strength of matrix matrix discont. spacing
groundwater	15	groundwater
discont. orientation adjustment	100	matrix discont. orientation adjustment.

to = 60 (!)

correlations exist between RMR and c, d etc...

Reinterpretation of case histories of bimrock materials may allow a correlation of volumetric proportion of blocks to these values of c, d etc.

Once a relationship has been established, **Test it!!**

How?

- Review landfills in Franciscan mélange, classify the rockmass, determine bimrock RMC rating, predict c, d .
- Check prediction against estimated c, d for case history, or do field mapping, back-analysis.

Formation of Mélanges

- The occurrence of mélangé bodies correlates well with the location of suspected convergent crustal plate boundaries (subduction zones). The details of plate tectonics/mélangé formation are complex.....
- A convergent plate boundary is generally:

Greater than 12 ways of forming mélanges (Lambert, 1988) — most related to processes in the 'off-scraping region' shown above.

Some concepts presented by Cowan, 1985.

- Within the accretionary complex, *Flow mélanges* may develop. (Cloos, 1984)

The flow channel develops due to viscosity contrasts between the relatively cool, wet sediments toward ocean plate, and drier, hotter, more indurated side on upper plate side.

Shear resulting from viscosity contrasts are accommodated by flow in the flow channel - result in 'plucking' of previously metamorphosed Sediments.

Prose in English
Class of 1945

Fully expanded the classification may appear like:

block dominated ← matrix-dominated →

Advantage of classification:

rocks of diverse lithology & genesis may share the same classification, and may have similar engineering behaviour: -

block in folded matrix: melange, olistostrome, mylonite

block in closely jointed matrix: melange, vlc. breccia, indurated talus

- The classification scheme allows a broader literature search
